1. INTRODUCTION

This service manual was prepared for use by Authorized Warranty Stations and contains service information for the Marantz Model 150 Stereophonic Tuner.

Servicing information and voltage data included in this manual are intended for use by the knowledgeable and experienced technician only. All instructions should be read carefully. No attempt should be made to proceed without a good understanding of the operation in the tuner.

The parts list furnishes information by which replacement parts may be ordered from the Marantz Company. A simple description is included for parts which can be usually obtained through local suppliers.

2. AM TUNER

The AM Tuner section in the 150 consists of one IC, including an RF amplifier, local oscillator mixer, IF amplifier, and detector, and three transistors, one of which comprises a signal strength indication amplifier and the other two comprise a detected audio signal amplifier.

All components except the tuning capacitor and ferrite bar antenna are mounted on the printed circuit board P150.

The AM signal induced in the ferrite bar antenna is fed to the RF amplifier input (pin 12) and amplified to the level required for overcoming the conversion noises, thus giving good S/N performance. The tuned circuit inserted in each of the output and input circuits of the RF amplifier assures very high image and spurious rejection performance.

Thus the amplified and selected AM signal is then applied to one Mixer input (pin ①). While the local oscillator voltage is injected to the other Mixer input (pin ⑥) through a capacitor C158. Then both AM signal and local oscillator voltage are mixed and converted into 455kHz intermediate frequency. The resulting IF signal is applied to the IF transformer L153 consisting of one ceramic filter and two tuned circuits.

The output of L153 is led to the IF amplifier input (pin ⑨) through a coupling capacitor C159 and amplified to the sufficient level to drive the detector. The detected audio signal derived from pin ⑦ is filtered and amplified, and the final audio output is obtained from the collector of H154 and applied to the output jacks through the function switch and OUTPUT LEVEL controllers RD15/RD16 and output amplifier HD01, HD02. The DC component of the detected IF signal is used as an AGC voltage to control emitter current of RF amplifier through the AGC amplifier incorporated in the IC. A part of the DC component is also led to the signal strength indication amplifier H152. The output appearing at the collector of H152 and is level adjusted by R169, indicated on the display scope H001 through vertical scope amplifier.

2.1 Suggestions for AM Tuner Troubleshooting

Symptom: No reception

Check for broken AM bar antenna, next try to tune stations by rotating the fly-wheel tuning knob slowly and observe the spot on the oscilloscope whether it deflects up and down or not. If the spot moves up and down as you tune past each station, no failure may exist in the stages at least preceding the detector circuit. Next connect a high sensitive oscilloscope to the J009-3 and check for the detected audio signals with the tuner correctly tuned to a station. If the spot does not moves up and down when you tune past each station, check the local oscillator circuit. Normal local oscillator output voltage at the hot end of the oscillator tuning capacitor is about 1.5 to 3 volts, depending upon the tuning capacitor position. When measuring the local oscillator output voltage use and RF VTVM, no circuit tester gives correct readings. If the local oscillator output voltage is normal, check all voltage distributions in the AM circuits by using a DC VTVM and compare the measured values with those given in the schematic diagram.

3. FM TUNER

3.1 RF and IF Circuits

The FM Tuner section in the Model 150 is divided into five functional blocks: FM Front End,

IF Amplfier, Detector, Muting Control and MPX Stereo Decoding Circuit.

An FM signal induced by the FM antenna is led to FM antenna coil L101 through the ANTENNA ATTENUATOR switch and Balun coil. The signal is then applied to the dual gate MOS FET RF amplifier which is turn feeds its output to the next dual gate MOS FET Mixer H102 through the triple tuned Butterworth type RF tank circuit. The Mixer converts its input signal into 10.7MHz intermediate frequency and amplifies it at the same time. The H103 is a local oscillator, the output of which is injected into the second gate of the dual gate MOS FET Mixer, through the coupling capacitor C113, the injection voltage being about 700mV. The 10.7MHz front end output is led to the next IF amplifier unit through the coaxial cable.

The IF amplifier unit consists of nine IF amplifier stages (including five IC limiter stages) and one AGC amplifier stage. Four pieces of phase linear IF block filter (one piece of six-pole filter and three pieces of four-pole filter) are also used to obtain high selectivity, and five IC limiter stages are also employed for the best limiting characteristics, improved capture ratio and AM good suppression.

A part of the FM Front End output is applied to the AGC amplifier H201, and the rectified output is fed back to the gate of the dual gate MOS FET RF amplifier to decrease the gain with increased signal strength. The second gate voltage of the dual gate MOS FET RF amplifier is varied by the AGC from about +3.0V at no incoming signal to about -0.5V at a strong incoming signal $(100K\mu V)$.

The signals required for multipath indication are obtained from the three IF amplifier stages through the coupling capacitors C220, C225 and C236 respectively and rectified by three pairs of full wave diode circuit. Thus obtained three AM components in the FM signal are appropriately mixed and applied to the vertical amplifier for multipath display.

The IF signal sufficiently amplified through each IF amplifier stage is finally fed to the detector amplifier unit. The detected audio output is led to the buffer amplifier HA02 and its buffered output is led to: (a) the noise amplifier H304 through the resistor R326 and capacitor C334, (b) the QUADRADIAL OUTPUT Jack on the rear panel through the resistor R333, (c) the MPX stereo decoding IC (H301) through R302 and C302.

3.2 MPX Stereo Decoding Circuit

The stereo composite signal from the buffer amplifier undergoes a phase compensation by R302 and C302, is led to the input terminal pin ② of the MPX stereo decoding IC H301 on a PLL (Phase Locked Loop) basis, and is decoded into the left and right stereo signals, which become available at pins 4 and 5, respectively. These decoded left and right stereo audio signals are introduced through a low pass filter consisting of L301 to L304 and C308 to C317 for elimination of undesirable residual switching signal and through a de-emphasis network consisting of R312, R313, C318 and C319 to the audio signal amplifier contained in the muting system IC (H302), where the signals are amplified to a required level for the output from J010-11 and J010-13. From these jacks, the audio signals are further led through the function switch and OUTPUT LEVEL controls RD15/RD16 into the output amplifiers HD01 and HD02, where are signals are amplified to be fed to the output terminals.

Figure 1 presents an internal block diagram showing the functions of the PLL basis MPX stereo decoding IC HA1156. The input stereo composite signal, amplified by the audio amplifier, is delivered to the phase detectors PD-1 and PD-2. A part of the stereo composite signal is also delivered to the stereo decoder section. The VCO (Voltage Control Oscillator) produces a free run oscillation in the neighborhood of 76kHz with the time constant determined by a capacitor C303 and resistors R304 and R305 set on the outside of pin (4). The VCO output has its frequency divided into 19kHz through the two frequency divider stages (DIV-1, DIV-2), and is reversed to the phase detector PD-1, which contains two input terminals designed to produce an output in proportion to the product of the two input signals.

The signal led to one PD-1 input is a 19kHz square wave formed through frequency division of the 76kHz VCO output signal by the two frequency divider stages DIV-1, and DIV-2, and the

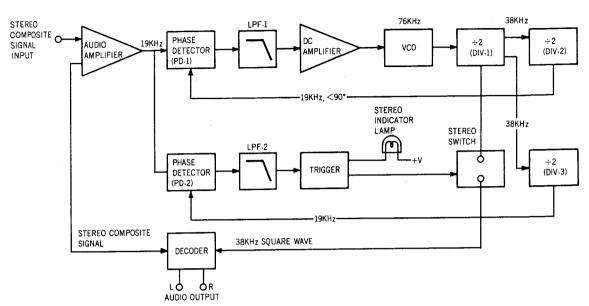

Figure 1. Block Diagram of the HA1156

19kHz pilot signal included in the stereo composite signal as a reference signal is led to the other PD-1 input. Therefore, the output of PD-1 which has passed through the low pass filter LPF-1 provides DC output voltage in proportion to the phase variance between the two inputs. This DC output voltage is amplified by the DC amplifier, and is supplied to the 76kHz VCO as a control voltage. This means that the output frequency and phase of the VCO have been phase-locked to the input pilot signal. The 38kHz sub-carrier reproduced by PLL, as stated above, is delivered through the stereo switch to the stereo decoder section as a switching signla, thus driving the decoder stage. One of the inputs of PD-2 is given the 19kHz resulting from the frequency division completed by DIV-1 and DIV-3, whereas the other input gets the 19kHz output contained in the composite signla, and the output is provided with a DC output in proportion to the amplitude of the pilot signal. This DC output is furnished through LPF-2 to the trigger amplifier which drives the stereo indicator lamp and stereo switch. Therefore, insufficient supply of the pilot signal results in failure to light the stereo indicator and to turn on the stereo switch located in the path of the 38kHz switching signal, thereby avoiding a wrong stereo operation.

H306 fitted on the outside of pin (8) is a switching transistor for automatic monaural-stereo switchover. When the intensity of an incoming signal from an FM station is weaker than a predetermined level, this H306 is turned on and pin (8) is grounded, thereby developing a condition for monaural reception. For a forced monaural operation, switch the MODE switch to "MONO", and H306 comes into the "On" state with the positive bias voltage applied to the base, and pin (8) is grounded, thereby establishing monaural operation.

The transistor H303 connected externally to pin 4 is intended to stop the 76kHz oscillation of the VCO which interferes an AM signal during the reception of an AM station. When the function switch is set to "AM" position, a positive bias is charged on the base of H303, H303 is turned on, and pin 4 is grounded. Thus, the oscillation of the VCO is stopped, ending the interference with AM reception.

3.3 Audio Muting and Stereo Mode Auto-Selecting Circuit

The muting circuit in the Model 150 consists of one muting system IC, containing almost all functions required for muting operation and 2-channel audio signal amplifier, and two transistors comprising a noise amplifier, and two transistors comprising a trigger voltage shaping circuit.

Three inputs control the muting function. The first is related to the signal strength, the second to the noise condition at the detector, and the third is driven from the DC component of the detector output. These inputs are properly matrixed and gated to provide muting free from noise and transients.

The first input is a DC voltage obtained by rectifying a part of the IF signal output, and is fed through the trigger voltage shaping circuit of H308 and H309 and R340 to the muting system IC (H302) pin ⑥. Pin ⑥ is connected to the base of the muting drive transistor Q19 through the Schmidt trigger and AND circuit within the IC(H302) (see Fig. 2).

The collector of the transistor Q19 is connected to the IC (H302) pin (§) within the IC, and is also connected through the MUTING switch, STEREO ONLY switch, R346, and R316 to the IC (H302) pin (②). Pin (②) is connected to the base of the muting transistors Q23 (for the L channel) and Q22 (for the R channel) within the IC. The collectors of Q23 and Q22 are connected to pins (①) and (③), respectively, within the IC. These pins are connected through the low-pass filter consisting of C321, C320, and L301 to L304 to the MPX stereo decoding IC (H301) output pins (4 (L channel) and 5 (R channel), respectively.

Each signal output of the MPX stereo decoding IC (H301) passes through the low-pass filter and respective capacitors C321 and C320, further passes through respective capacitors C324 and C323, and is then fed to the respective audio signal amplifier input pins ① (L channel) and ① (R channel) on the muting system IC (H302). Each audio signal amplifier magnifies the input signal by approximately 20dB and feeds the output signal to the respective pins ② (L channel) and ③ (R channel).

If the IF output signal is greater than the muting threshold level predetermined with the MUTING LEVEL CONTROL switch, the transistor Q19 is turned on by the DC voltage obtained by rectifying a part of the IF output signal led from J010-1 through H309 and H308 to the muting system IC (H302) pin ⑥. Turning on Q19 decreases its collector potential, resulting in turning off the muting switching transistors Q23 and Q22. The MPX stereo decoding IC (H301) output signals, therefore, passes through the low-pass filters and de-emphasis circuits and come to the muting system IC (H302) pins ① and ① without any attenuation in the route. The output signals are then amplified by the audio signal amplifier in the IC (H302) and are fed out of the pins ② and ③ .

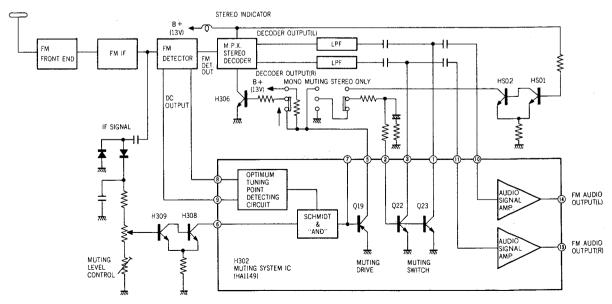

Figure 2. Block Diagram of the Muting System

If the IF output signal is lower than the muting threshold level predetermined with the MUTING LEVEL CONTROL switch, the transistor Q19 keeps the off state and its collector voltage (at the pin 5) near the +B voltage (+13V) turns Q23 and Q22 on. Turning on these transistors reduces their corrector-emitter resistances to zero (0) ohm, thereby bypassing the MPX stereo decoding IC (H301) output signals to the ground. The MPX stereo decoding IC (H301) outputs, therefore, cannot come to the muting system IC (H302) pins 1 and 1, thus no output signals appearing at the pins 4 and 3.

This is the fundamental principle of the muting operation but for more elaborate muting operation, the second and the third inputs are necessary.

The second input is used to protect the muting operation and MPX stereo beacon lamps from misoperation due to undesirable noises. The high frequency noises included in the detected audio signals are separated by a small capacitor C334 and are amplified by the noise amplifier transistor H304. Its output is rectified by the two diodes. The rectified DC output is proportional to the noise components in the audio signals.

When there are excessive noises in the audio signals such as obtained with a station incorrectly tuned in, the rectified DC output turns the transistor H305 on, decreasing the emitter-collector resistance to zero. This means pin (6) of H302 is short-circuited to the ground, therefore is turned off and any audio signals having excessive high frequency noises can not go through the path to pin (10) and (11)

The collector (pin §) of the transistor Q19 is also connected through the MONO switch to the transistor H306 led to the MPX stereo decoding IC (H301)pin ®, and turns it on. Pin ® is therefore grounded equivalently to set the IC in the monaural mode of operation. This prevents misoperation due to undesirable noises when the FM tuner is out of tuning.

When the MONO switch is depressed, an external bias is applied to the base of H306, which keeps the on state irrespective of the strength of the IF output signal and grounds pin ® of H301, thus maintaining the monaural mode of operation at any time.

The third input is fed from the FM discriminator. Since the FM discriminator of the Model 150 is DC floated, the FM discriminator DC output, called the "S" curve, is obtained both from JA01-1 and JA01-2, the polarities at which are inverse from each other (see Fig. 3).

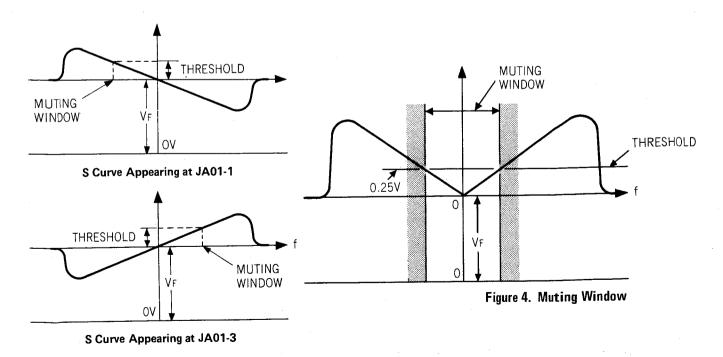

Figure 3. Discriminator DC Output

The DC output voltages are led to the "optimum tuning point detecting circuit" input pins and , respectively, of the muting system IC (H302). The output of the "optimum tuning point detecting circuit is fed through the "AND circuit" to the base of the muting driving transistor Q19. If the DC voltage applied to the muting system IC (H302) pin 8 or 9 becomes higher than 0.25V, Q19 is turned off, which turns Q23 and Q22 on for muting operation (see Fig. 4).

Thus, when the tuning is shifted or deviated at which undesirable noisy side-audio signals are produced, both muting and monaural/stereo driving transistors Q19 are operated automatically and short-circuited to the ground.

3.4 "Stereo Only" Circuit

The Model 150 provides a capability of selecting and receiving FM stereo broadcast signals only. This function is given by depressing the STEREO ONLY pushswitch. With the pushswitch depressed, the bases (pin ②) of the muting switching transistors Q23 and Q22 are connected through the trigger amplifier of HS02 and HS01 to the MPX stereo decoding IC (H301) stereo indicator lamp drive pin ⑥ (see Fig. 2).

When the stereo indicator lamp illuminates with the Model 150 tuning a stereo broadcast station correctly, the potential at the MPX stereo decoding IC (H301) pin ⑥ is very low (near zero (0) volt) since the internal stereo indicator lamp driving transistor turns on. HS01, therefore, turns off and HS02 turns on, lowering its collector potential down. This maintains Q23 and Q22 in the muting system IC (H302) in the off state, allowing the stereophonic audio signal output to appear at the H302 pins ④ and ⑤ normally.

If the Model 150 tunes a monaural station, the stereo indicator lamp does not illuminate, and the potential at the IC (H301) pin (6) becomes higher (+13V). This turns HS01 on and HS02 off and turns Q23 and Q22 in H302 on, causing the muting action. Thus, no audio signal outputs appear at pins (4) and (13). This means all signals except stereo broadcast signals can be muted out.

3.5 Suggestion for Troubleshooting FM Tuner

3.5.1 Symptom: No FM Reception

Turn on (depress) two SCOPE DISPLAY switches "ON" and "TUNING".

First try to tune to some FM stations.

Rotate the fly-wheel tuning knob slowly and observe the spot on the oscilloscope whether or not if follows an approximately rectangular path as you tune past each station. If it moves as described, the tuner circuits preceding the discriminator circuit may have no failure. If not, there would be some defects in the front end or IF amplifier stages, or oscilloscope circuits. To localize the defects in the former case, check the FM local oscillator circuit, using an RF VTVM. The normal local oscillator voltage is one or two volts (rms) at the tuning capacitor, depending on the tuning capacitor position. If the local oscillator voltage is normal, then check all voltage distribution in the front end and IF amplifier stages and compare them with those shown in the circuit diagram.

For localizing the defects in the latter case it is one of methods to apply an audio signal to the SCOPE INPUTS jack (FRONT L or R) on the rear panel with the "EXT 2 CH" SCOPE DISPLAY switch depressed.

The detected audio signals can also be checked by depressing the SCOPE DISPLAY switch "AUDIO" if the scope circuit operates without any defects.

3.5.2 Symptom: No Stereo Separations

First verify that the "MONO" switch is in normal out position.

Connect an FM RF signal generator output modulated by a stereo modulator to the rear FM ANTENNA terminals, and check whether the stereo beacon is turned on or not. If not turned on, check the 19kHz VCO output signal (R311), using an oscilloscope and frequency counter.

4. SCOPE DISPLAY CIRCUIT

Refer to the operating manual on general operating instructions for "SCOPE DISPLAY".

4.1 External Display (2 CH, 4 CH)

a. 2 CH Display

The signal coming into the SCOPE INPUTS terminal FRONT L (FRONT R) on the rear panel is displayed on the scope through the following signal path.

SCOPE INPUTS FRONT L (FRONT R) terminal \rightarrow R002 (gang variable resistor) \rightarrow Pin terminal JT06 (JT03) \rightarrow CT06 (CT08, 0.01 μ F) \rightarrow RT28 (RT30, 100 K Ω) \rightarrow HT05 (HT07, FET) \rightarrow CT10 (CT12, 10 μ F) \rightarrow 2 CH DISPLAY switch \rightarrow RT19 (RT20, 270 K Ω) \rightarrow Pin connectors J006-8 and J902-8 (J006-6 & J902-6) \rightarrow Vertical amplifier (Horizontal Amplifier).

b. 4 CH Display

For the 4 CH display is used a diode matrix circuit consisting of four diodes and twelve resistors. In this circuit, the signals coming into the SCOPE INPUTS terminals FRONT L and R and REAR L and R are arranged to have the same polarity on the positive side and are halved. In turn, the signals are led to the positive or negative side of the differential scope amplifier, in which the signals are individually vector composed and displayed.

Now, the signal path of each channel will be shown when the signals of the same phase and same level are fed to the channels at different times.

- b-1 SCOPE INPUTS terminal FRONT L \rightarrow R002 (Gang variable resistor) \rightarrow Pin terminal JT06 \rightarrow CT06 (0.01 μ F) \rightarrow RT28 (100 K Ω) \rightarrow HT05 (FET Pre-Amplifier) \rightarrow CT10 (10 μ F) \rightarrow 2 CH DISPLAY switch \rightarrow HT04 (Diode) \rightarrow RT14 (5.6 K Ω) \rightarrow 4 CH DISPLAY switch \rightarrow 2 CH DISPLAY switch \rightarrow Pin connectors J006-8 & J902-8 \rightarrow Vertical Amplifier (plus side).
 - \hookrightarrow RT15 (5.6 KΩ) \rightarrow 4 CH DISPLAY switch \rightarrow Pin connectors J006-5 & J902-5 \rightarrow Horizontal Amplifier (minus side).
- b-2 SCOPE INPUTS terminal REAR L \rightarrow R003 (Gang variable resistor) \rightarrow Pin terminal JT07 \rightarrow CT07 (0.01 μ F) \rightarrow RT29 (100 K Ω) \rightarrow HT06 (FET Pre-Amplifier) \rightarrow CT11 (10 μ F) \rightarrow HT02 (Diode) \rightarrow RT08 (5.6K Ω) \rightarrow 4 CH DISPLAY switch \rightarrow Pin connectors J006-9 & J902-9 \rightarrow Vertical Amplifier (minus side) .
 - \rightarrow RT09(5.6 K Ω) \rightarrow 4 CH DISPLAY switch \rightarrow Pin connectors J006-5 & J902-5 \rightarrow Horizontal Amplifier (plus side).
- b-3 SCOPE INPUTS terminal FRONT R \rightarrow R002 (Gang variable resistor) \rightarrow Pin terminal JT03 \rightarrow CT08 (0.01 μ F) \rightarrow RT30 (100 K Ω) \rightarrow HT07 (FET Pre-Amplifier) \rightarrow CT12 (10 μ F) \rightarrow 2 CH DISPLAY switch \rightarrow HT03 (Diode) \rightarrow RT10 (5.6 K Ω) \rightarrow 4 CH DISPLAY switch \rightarrow 2 CH DISPLAY switch \rightarrow Pin connectors J006-6 & J902-6 \rightarrow Horizontal Amplifier (plus side).
 - \rightarrow RT11 (5.6 K Ω) \rightarrow 4 CH DISPLAY switch \rightarrow 2 CH DISPLAY switch \rightarrow Pin connectors J006-8 &J902-8 \rightarrow Vertical Amplifier (plus side).
- b-4 SCOPE INPUTS terminal REAR R \rightarrow R003(Gang variable resistor) \rightarrow Pin terminal JT10 \rightarrow CT09 (0.01 μ F) \rightarrow RT31 (100 K Ω) \rightarrow HT08 (FET, Pre-Amplifier) \rightarrow CT13 (10 μ F) \rightarrow HT01 (Diode) \rightarrow RT04 (5.6 K Ω) \rightarrow 4 CH DISPLAY switch \rightarrow 2 CH DISPLAY switch \rightarrow Pin connectors J006-6 & J902-6 \rightarrow Horizontal Amplifier (plus side).
 - \hookrightarrow RT05 (5.6 K Ω) \rightarrow 4 CH DISPLAY switch \rightarrow Pin connectors J006-9 & J902-9 \rightarrow Vertical Amplifier (minus side).

4.2 AM Tuning Display

AM signal strength and the correct tuning point are displayed on the scope through the following signal routine:

Rectified DC output at Pin connector J009-9 \rightarrow FM push switch TUNING DISPLAY switch \rightarrow RT16 (270 K Ω) \rightarrow EXT. 4 CH DISPLAY switch \rightarrow EXT. 2 CH DISPLAY switch \rightarrow Pin connectors J006-8 & J902-8 \rightarrow H903 Vertical Amplifier.

4.3 FM Tunig Display

FM signal strength and correct center tuning signals are applied to the oscilloscope's vertical and horizontal deflection plates through the following routines;

- a. Rectified DC output for FM signal strength at the C250 \rightarrow Pin connector J010-41 \rightarrow R337 (33 K Ω) \rightarrow H307 buffer amplifier \rightarrow R339 (trimming resistor) \rightarrow Pin connector J010-43 \rightarrow FM push switch \rightarrow TUNING DISPLAY switch \rightarrow RT16 (270 K Ω) \rightarrow EXT. 4 CH DISPLAY siwtch \rightarrow EXT. 2 CH DISPLAY switch \rightarrow Pin connectors J006-8 & J902-8 \rightarrow Vertical Amplifier (for signal strength).
- b. DC plus and minus output for center tuning at the Pin connector JA01-3 → Pin terminal JT11 → MULTIPATH DISPLAY switch → RT22 (270 KΩ) → EXT. 4 CH DISPLAY switch → EXT. 2 CH DISPLAY switch → Pin connectors J006-6 & J902-6 → Horizontal amplifier (for center tuning).
 - Note 1. CT05 is a filtering capacitor for audio signals.
 - Note 2. For easy-to-see spot display, the display spot is modulated to have a slight length in vertical direction for FM tuning or in horizontal direction for AM tuning. This is done by applying a small amount of AC voltage for pilot lamps to the Vertical (for FM) or Horizontal (for AM) Amplifier input terminal J902-10 or J902-4.

AC voltage for pilot lamps \rightarrow RT23 \rightarrow CT01 \rightarrow TUNING DISPLAY switch FM pushswitch \rightarrow J902-10 (for FM) or J902-4 (for AM).

* R815 is the DC bias adjusting resistor which corrects the spot position at no signal.

4.4 FM Multi-Path Display

The multi-path display circuit is almost the same as the FM TUNING DISPLAY circuit except the following.

- a. AC voltage for tuning spot modulation is cut off (RT23 and CT01 are disconnected) from the circuit by depressing the MULTI-PATH pushswitch.
- b. Audio signal pass filter (CT05) is also cut off. This means audio signals developed at JA01-3 are fed to the horizontal amplifier.

The vertical signal which contains multi-path information is the same as that of signal strength and led to R339 through the C250.

5. SCOPE CIRCUIT DESCRIPTION

5.1 Vertical Amplifier

The vertical amplifier consists of two direct-coupled differential amplifier stages, the first stage using two FET's (H903, H904) and the second two transistors (H907, H908).

The Vertical Amplifier amplifies signals from DC to AC frequency with very high stability.

The first differential amplifier operates as a source follower and no voltage gain is obtained.

The signal passed the first stage is directly fed to and amplified by the second stage. The gain of the second stage is 47dB for DC signal and 39dB for AC signal. The finally amplified signal is then delivered to the oscilloscope tube.

- * R916 is a gain adjusting resistor and should be set for the gain of 34mV/cm (at 1kHz, 2 CH DISPLAY position).
- * R906 is provided for adjusting DC balance between H903 and H904 and should be set so that the voltage difference between the source terminals of H903 and H904 is less than 0.05V with the vertical centering control knob placed in its mechanical center.

5.2 Horizontal Amplifier

The circuitry of the horizontal amplifier is almost the same as that of the vertical amplifier.

* R915 is a gain adjusting resistor and should be set for 34mV/cm (at 1kHz, 2 CH DISPLAY position).

* R905 is the DC balance control between H901 and H902 and should be set so that the voltage difference between source terminals of H901 and H902 is less than 0.05V with the horizontal centering control knob placed in its mechanical center.

6. POWER SUPPLY CIRCUIT

- 6.1 Power source for tuner (+13.5V) and stereo beacon (+12.5V) is zener-regulated and then filtered by a transistor ripple filter circuit consisting of H801.
- 6.2 Power source for Pre-Amp (+36V) is fed through a transistor ripple filter circuit consisting of H802.
- 6.3 Both plus and minus 13.5V DC for the first differential amplifiers are regulated by two zener diodes, H805 and H804, respectively. The same plus 13.5V DC is also used for the external scope amplifier.
- 6.4 Plus 120V DC for the collector circuit of the vertical and horizontal amplifier and minus 970V DC for the CRT's anode are fed by the power supply circuit on P900.
- 6.5 Power sources (plus and minus) for the trace rotation are fed through a resistor R813 and R812 in the power supply circuit on P800.

7. TROUBLE SHOOTING OF OSCILLOSCOPE CIRCUIT

7.1 Symptom: No spot obtained

If no spot is obtained with the CENTERING knobs (V and H) placed in their mechanical center and the BRIGHT control on the rear panel at maximum, there would be defects in the CRT's circuit, vertical and/or horizontal amplifier. To localize the defects proceed as follows:

- a. Short both collector terminals of H907 and H908 and if the spot appear, the vertical amplifier would be defective.
- b. Short both collector terminals of H905 and H906 and if the spot appear, the horizontal amplifier would be defective.
- c. If no spot is obtained yet, the CRT circuit would be defective.

7.2 Symptom: Blurred spot

First adjust the FOCUS control on the rear panel and if no sharp spot is obtained, check whether the voltage between CRT cathode (No. 3 terminal) and plate (No. 4 terminal) can be varied from 44V to 420V or not by adjusting the FOCUS control on the rear panel. If the voltage varies within the limit above, the oscilloscope circuit is normal. Try to replace the CRT with new one.

CAUTION

1. Do not leave the scope turned on with BRIGHT control set maximum.

Do not make the spot left for a long time with its brightness maximum and its focus pin-pointed to avoid possible desensitivity of the phosphor. In the case where the scope has to be turned on for a long time, decrease the brightness of the spot. Turn the scope off when not in use.

2. High Voltage, Danger

When removing the top and/or bottom cover, be sure to remove the power cord from the AC outlet to avoid possible electrical shock from high voltages of the oscilloscope circuit.

3. Do not place the set (CRT) in a powerful magnetic field.

If placed, the electron beam in the CRT will be bent and the spot is shifted from the correct position. The trace may also be distorted.

8. SCOPE DISPLAY ALIGNMENT

- 8.1 Depress both SCOPE DISPLAY switches "ON" and "EXT. 2 CH".
- 8.2 Adjust two CENTERING knobs to bring the spot into the center of small circular.

Personal IV.

- 8.3 Adjust the "BRIGHT" control (R005) on the rear panel to make the brightness of the spot dimmer.
- 8.4 Adjust the "FOCUS" control (R004) to make the spot smaller and more circular.
- 8.5 Feed in 130mV (1kHz) to the "SCOPE INPUTS, FRONT R" jack and adjust R915 (HORIZ) to obtain a horizontal deflection of about 4cm, then connect the same input voltage to the "VERT" jack and adjust R916 (VERT) for the same vertical deflection.
- 8.6 Set both the centering knobs to their mechanical center, and adjust R905 (HORIZ) and R906 (VERT) to bring the spot into the center of small circular.

9. AM TUNING DISPLAY ALIGNMENT

- 9.1 Depress both SCOPE DISPLAY switches "ON" and "TUNING" and MODE SELECTION switch "AM".
- 9.2 Adjust R815 to bring the spot on the lower center of the base line with no station tuned in.

10. FM TUNING DISPLAY ALIGNMENT

- 10.1 Depress both SCOPE DISPLAY switches "ON" and "TUNING" and MODE SELECTION switch "FM".
- 10.2 Connect an FM signal input of $100 \text{K}_{\mu}\text{V}$ (98MHz, 400Hz, 30% Mod.) to the FM ANTENNA terminals and adjust so that the spot does not frame out.
- 10.3 FM Multipath display alignment: Adjust RA24 to obtain full deflection of the trace within both side marks, applying an FM signal ($1K\mu V$, 400Hz, 100% Mod.) to the FM ANTENNA terminals.

11. AM ALIGNMENT

AM IF Alignment:

- 11.1 Connect a sweep generator to J009-15 and alignment scope to the J009-3.
- 11.2 Rotate the core of the IF transformer L153 for maximum height and flat top symmetrical response.

AM Frequency Range and Tracking Alignment:

- 11.3 Set an AM signal generator to 515kHz. Turn the tuning capacitor fully closed (place the tuning pointer at the low end.) and adjust the oscillator coil L152 for maximum audio output.
- 11.4 Set the signal generator to 1650kHz. Place the tuning pointer in the high frequency end and adjust the oscillator trimmer on the oscillator tuning capacitor for maximum audio output.
- 11.5 Repeat Steps 11.3 and 11.4 until no further adjustment is necessary.
- 11.6 Set the generator to 600kHz and tune the receiver to the same frequency. Adjust a slug core of the AM ferrite rod antenna and RF coil L151 for maximum output.
- 11.7 Set the generator to 1400kHz and tune the receiver to the same frequency. Adjust both trimming capacitors of the Antenna and RF tuned circuit for maximum output.
- 11.8 Repeat Steps 11.6 and 11.7 until no further adjustment is necessary.
 Note: During tracking alignment, reduce the signal generator output as necessary to avoid AGC action.
- 11.9 AM Signal Strength Display Adjustment: Set the AM signal generator to 1000 kHz, $100 \text{K} \mu \text{V}$ and adjust R169 so that the spot may meet upper mark.

12. FM ALIGNMENT

12.1 Connect an FM signal generator to the FM ANTENNA terminals and an oscilloscope and an audio distortion analyzer to the TUNER OUTPUT jacks on the rear panel.

- 12.2 Set the generator to 87.4MHz and provide about 3 to $5\mu V$ output. Place the tuning pointer at the low frequency end by rotating the tuning knob and adjust the core of the oscillator coil L105 to obtain maximum audio output.
- 12.3 Set the generator to 108.6MHz and provide about 3 to 5μV output. Rotate the tuning knob and place the tuning pointer at the high frequency end. Adjust the trimming capacitor C105 for maximum output.
- 12.4 Repeat Steps 12.2 and 12.3 until no further adjustment is necessary.
- 12.5 Set the generator to 90MHz and tune the receiver to the same frequency. Decrease the signal generator output until the audio output level decreases with the decreasing generator output. Adjust the antenna coil L101, RF coils L102, L103 and L104 and IF transformer L106 for minimum audio distortion.
- 12.6 Set the generator to 106MHz and tune the receiver to the same frequency. Adjust the trimming capacitor C101, C102, C103 and C104 for minimum distortion.
- 12.7 Repeat Steps 12.5 and 12.6 until no further adjustment is necessary.
- 12.8 Connect a VTVM (with DC 1V range) across the pin connector JA01-3 and common ground. Adjust the secondary core (upper) of the discriminator transformer LA01 so that the VTVM indicates null reading (zero reading) at no signal. Set the generator to 98MHz and increase its output level to $1K\mu V$ and tune the receiver to the same frequency so that the VTVM gives null reading. Next adjust the primary core (bottom) of LA01 for minimum distortion. (Scope display can, of course, be used as tuning indicator instead of the VTVM, if the scope unit has been correctly adjusted as instructed in the SCOPE DISPLAY ALIGNMENT.)

13. STEREO SEPARATION ALIGNMENT

- 13.1 Set an FM signal generator to provide $1K\mu V$ at 98MHz. Tune the receiver to the same frequency so that the tuning pointer indicates its center. Then, turn off the modulation of the generator. Connect a frequency counter to the test point R311 (point ©) and adjust R304 so that the frequency counter may precisely read 19kHz.
- 13.2 Modulate the generator with a stereo composite signal consisting of only L or R channel (pilot signal must be included).
- 13.3 Adjust the trimming resistor R302 for maximum and same separation in both channels.

14. FM DOLBY LEVEL ADJUSTMENT

- 14.1 Set an FM signal generator to provide a 400Hz, 50% modulated 1KμV output.
- 14.2 Connect the generator to the FM ANTENNA terminals and connect a VTVM to the TUNER OUTPUT jacks on the rear panel.
- 14.3 Depress the MODE SELECTION switches "FM" and "DOLBY FM" in and depress the SCOPE DISPLAY switches "ON" and "TUNING" in.
- 14.4 Set the generator to 98MHz and tune the receiver to the same frequency. Adjust and lock RS02 and RS01 until the VTVM connected to L CH and R CH outputs may read 580mV.

15. TEST EQUIPMENT REQUIRED FOR SERVICING

Table 1 lists the test equipment required for servicing the Model 150 Tuner.

| Item | Manufacturer and Model No. | Use |
|---------------------|---|---|
| AM Signal Generator | | Signal source for AM alignment. |
| Test Loop | | Used with AM Signal generator. |
| FM Signal Generator | Less than 0.3% distortion. | Signal source for FM alignment. |
| Stereo Modulator | Less than 0.3% distortion. | Stereo separation alignment and trouble shooting. |
| Frequency Counter | | MPX oscillator Adjustment (VCO). |
| Audio Oscillator | Weston Model CVO-100P, less than 0.02% residual distortion is required. | Sinewave and squarewave signal source. |
| Oscilloscope | High sensitivity with DC horizontal and vertical amplifiers. | Waveform analysis and trouble shooting. |
| VTVM | With AC, DC, RF range. | Voltage measurements. |
| Circuit Tester | | Trouble shooting. |

17. TECHNICAL SPECIFICATIONS

| FM SECTION | • |
|---|---|
| Quieting Slope | $1.7\mu V$ for 30dB, $5\mu V$ for 57 dB |
| Quieting Stope | $10\mu V$ for 62dB, $50\mu V$ for 70dB |
| Ultimate Quieting | 50uV for 70dB |
| Ultimate Quieting | Alternate channel better than 85dB |
| Selectivity | Alternate charmer, better than 15dB |
| Capture Ratio | Better than 1.50b |
| Stereo Separation | 40dB at 1KHz, 2/dB at 15KHz |
| Total Harmonic Distortion | Stereo: Less than 0.3% |
| | Mono: Less than 0.2% |
| Frequency Response | $\dots \dots \pm 1dB$, 30Hz to 15KHz |
| Total Sourious Rejection | Better than 100dB |
| Image Rejection | Better than 100dB |
| AM Suppression | Better than 60dB |
| IF Rejection | Retter than 100dB |
| Tr Rejection | 300ohm Balanced 75ohm unbalanced |
| Antenna Impedance | 250mV 15Kohms for +75KHz Dev |
| Quadradial Output | 350mv, 15Komms for ±75Km2 56v. |
| | |

NOTE

SERVICE INFORMATION FOR EUROPEAN MODEL

The information contained here in inclued the rear panel and main chassis component locations, schematic diagram, parts list, voltage conversion and FTZ regulations. For the circuit description, alignment method and repairing hints, refer to the original service

manual.

VOLTAGE CONVERSION

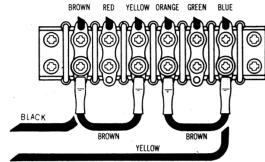

This model is equipped with a universal power transformer to permit operation at 110, 120, 220 and 240 V AC 50 to 60 Hz.

To convert the unit to the required voltage perform the following steps:

- (1) Remove the lid (top).
- (2) Change the jumper wires as illustrated below for the required AC voltage.

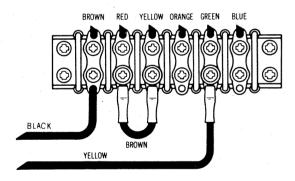

CAUTION: DISCONNECT POWER SUPPLY CORD FROM AC OUTLET BEFORE CONVERTING VOLTAGE.

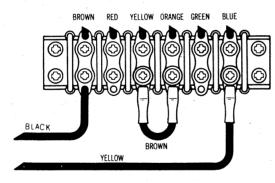

For 110V Operation

For 120V Operation

For 220V Operation

For 240V Operation

Figure 26. Voltage Conversion Chart

FTZ REGULATION

Instruction for the use in the range other than specified in FTZ codes

Achtung für die Leute, die in dem Gebiet wohnen, wo die FTZ-Bestimmungen vorherrschend sind.

Sollte das Gerät auch für Frequenzen auszerhalb des in den FTZ-Bestimmungen angegebenen Bereiches empfangebereit sein, bitten wir, den Bereich durch Nachstellen des Kernes in der Oszillatorspule (in der Abbildung mit "FTZ" gekennzeichnet) so zu korrigieren, dass er den Bestimmungen entspricht.
